

Dear Sirs,

When I was an engineering student I took a course on power systems. They said that the largest any single component should be in a system is 5% of the total. Making something bigger than this makes the system vulnerable if that one component should fail.

You can see an example of this unfolding in New York City right now. They lost 15% of their office space to two well chosen strikes.

Making our country centralized enough to be that vulnerable is very short sighted. I urge you to err on the side of decentralization, for the sake of the systems survival potential.
